

## Finding the Best Fit Axis-aligned Ellipse through a Set of Points

*Paul Nathan 24/06/2015*

Consider a set of  $n$  points on the plane, what axis-aligned ellipse with radii along the  $x$  and  $y$  axes of  $r_x$  and  $r_y$  respectively and centre  $(x_c, y_c)$  best fits these points?

The equation for the axis-aligned ellipse is given by

$$\frac{(x - x_c)^2}{r_x^2} + \frac{(y - y_c)^2}{r_y^2} = 1$$

Setting  $\alpha = \frac{r_x}{r_y}$  and multiplying through by  $r_x^2$  gives

$$(x - x_c)^2 + \alpha^2 (y - y_c)^2 = r_x^2$$

This may be expanded as follows, with a view to formulating a matrix equation for the four unknowns

$$2xx_c + 2\alpha^2 yy_c - \alpha^2 y^2 + r_x^2 - x_c^2 - \alpha^2 y_c^2 = x^2$$

In matrix form

$$\begin{pmatrix} x_0 & y_0 & -y_0^2 & 1 \\ & & & \\ & & & \\ & & & \\ x_{n-1} & y_{n-1} & -y_{n-1}^2 & 1 \end{pmatrix} \begin{pmatrix} 2x_c \\ 2\alpha^2 y_c \\ \alpha^2 \\ r_x^2 - x_c^2 - \alpha^2 y_c^2 \end{pmatrix} = \begin{pmatrix} x_0^2 \\ \\ \\ x_{n-1}^2 \end{pmatrix}$$

A minimum of four points is required to solve this exactly; otherwise (and more generally) the least-squares solution can be found by first multiplying through by the transpose of the coefficient matrix to turn  $\mathbf{A}$  into a  $4 \times 4$  square matrix, and then solving in the usual manner

$$\begin{aligned} (\mathbf{A}^T \mathbf{A}) \mathbf{X} &= \mathbf{A}^T \mathbf{B} \\ \mathbf{X} &= (\mathbf{A}^T \mathbf{A})^{-1} (\mathbf{A}^T \mathbf{B}) \end{aligned}$$

The circle centre coordinates and radius are obtained from the solution vector  $\mathbf{X}$

$$\begin{aligned}
\alpha &= \sqrt{X_2} \\
(x_c, y_c) &= \left( \frac{X_0}{2}, \frac{X_1}{2\alpha^2} \right) \\
r_x &= \sqrt{X_3 + x_c^2 + \alpha^2 y_c^2} \\
r_y &= \frac{r_x}{\alpha}
\end{aligned}$$

An alternative iterative method that yields the same result is the Gauss-Newton method. This non-linear regression method uses the gradient of the level set function  $F$  to find its minimum

$$F(x_c, y_c, r_x, r_y) = \frac{(x - x_c)^2}{r_x^2} + \frac{(y - y_c)^2}{r_y^2} - 1 = 0$$

$$\nabla F(x_c, y_c, r_x, r_y) = \begin{pmatrix} \frac{\partial F}{\partial x_c} \\ \frac{\partial F}{\partial y_c} \\ \frac{\partial F}{\partial r_x} \\ \frac{\partial F}{\partial r_y} \end{pmatrix} = \begin{pmatrix} -\frac{2(x - x_c)}{r_x^2} \\ -\frac{2(y - y_c)}{r_y^2} \\ -\frac{2(x - x_c)^2}{r_x^3} \\ -\frac{2(y - y_c)^2}{r_y^3} \end{pmatrix}$$

The iteration step is as follows, for vector function  $\mathbf{F}$  (consisting of  $n$  equations ( $n \geq 4$ ) for each set of points  $(x_i, y_i)$  that will have the ellipse fitted to them) and parameter vector  $\mathbf{X} = (x_c \quad y_c \quad r_x \quad r_y)^T$

$$\mathbf{X}_{j+1} = \mathbf{X}_j + (\mathbf{J}^T \mathbf{J})^{-1} (\mathbf{J}^T \mathbf{F}(\mathbf{X}_j))$$

The Jacobian matrix is

$$\mathbf{J}_j = \begin{pmatrix} (\nabla F_0)^T \\ \vdots \\ (\nabla F_{n-1})^T \end{pmatrix}_j = \begin{pmatrix} \frac{\partial F_0}{\partial x_c} & \frac{\partial F_0}{\partial y_c} & \frac{\partial F_0}{\partial r_x} & \frac{\partial F_0}{\partial r_y} \\ \vdots & \vdots & \vdots & \vdots \\ \frac{\partial F_{n-1}}{\partial x_c} & \frac{\partial F_{n-1}}{\partial y_c} & \frac{\partial F_{n-1}}{\partial r_x} & \frac{\partial F_{n-1}}{\partial r_y} \end{pmatrix}_j$$

Where  $F_i$  is evaluated using the current ( $j^{\text{th}}$ ) estimate of the parameters
